Initial Planning

Today is the start of our Web Project 1 and we had our introduction of what to achieve and what to expect.

After the class, I started conceptualizing what kind of project I will build. The initial phase is always the hardest. I have a few options: I was thinking of building a job tracker, a medical appointment scheduling application or e-commerce.

To wrap things up, I spent the rest of the time researching for inspiration.

Defining the Project Scope

I decided to build a medical appointment scheduling application. At first, I felt unsure about what features to include, so I used the inspiration I found yesterday as a starting point and will build it from there.

The initial core features will include user authentication (login and logout), the patient's portal for booking and viewing appointments, and interface for medical professionals to manage appointment requests and schedules. While I have not finalized every feature, I expect additional ideas and improvements to emerge as I continue designing and implementing the system.

Here is the link of the case study where I based my project. Although I am not building all that is written on it. I just want to share that this is where I got my ideas from. I haven't build it and I am using this project to use the learned skills to build it

System Planning

Today, I reviewed the project requirements to ensure that my application meets each one. The most challenging part so far has been the Figma design. I don't think three days is enough to create a complete low-fidelity wireframe, so for now I am focusing on planning the application's structure instead. I identified the main pages that the system will need, including the Home page, Login page, Patient Portal, and Medical Professional dashboard. Although I have not created the wireframes yet, having these pages planned gives me a clear direction for the next stage of the project.

I also designed the initial database structure. At this stage, I am keeping it relatively simple since the application only needs to demonstrate the required functionality. In a real-world medical appointment scheduling system, the database would typically be much more complex, with multiple related tables for patients, healthcare professionals, appointments, availability, medical records, and other supporting data. For this project, however, I am focusing on a clean and manageable database design that meets the course requirements while leaving room for future enhancements.
